0.1 Inverses of Functions

Definition. Inverse of a function

Suppose $f: X \to Y$, $g: Y \to X$ is an inverse to f (soon we'll prove that inverses are unique if they exist) if $f \circ g$ and $g \circ f$ are the identity. In other words, $(g \circ f)(x) = x$, $(f \circ g)(y) = y$ for all $x \in X$, $y \in Y$.

Theorem — $Bijective \iff Inverse$

For $f: X \to Y$, f is a bijection if and only if f has an inverse.

Proof. Suppose f has an inverse function g. Then $f \circ g$ and $g \circ f$ are the identity. Suppose f(a) = f(b). Then

$$f(a) = f(b)$$

$$g(f(a)) = g(f(b))$$

$$(g \circ f)(a) = (g \circ f)(b)$$

$$a = b.$$

Thus f is injective.

Suppose $b \in Y$. Since $f \circ g$ is the identity, we have that $(f \circ g)(b) = b$, so f(g(b)) = b. Thus f is surjective. Therefore f is a bijection.

Now suppose that f is a bijection. We define $f^{-1}(a)$ by $f^{-1}(a) = b$, where a = f(b).

- Because f is surjective, we have that for all $a \in Y$, there exists some $b \in X$ such that a = f(b).
- Because f is injective, any $a \in Y$ is uniquely mapped by some $b \in X$.

Thus f^{-1} is a function. We will now show that f^{-1} is the inverse of f. For all $x \in X$, $(f^{-1} \circ f)(x) = x$ by definition. For all $y \in Y$,

$$\begin{split} (f\circ f^{-1})(y) &= f(f^{-1}(y))\\ &= f(f^{-1}(f(x)))\\ &= f(x)\\ &= y. \end{split} \tag{Because f is surjective)}$$

Therefore f^{-1} is the inverse of f.

Theorem — Uniqueness of Inverses

Inverses of functions are unique, provided they exist.

Suppose $f: X \to Y$. If f has inverses $g, h: Y \to X$ such that $g \circ f = h \circ f = \mathrm{id}_X$, $f \circ g = f \circ h = \mathrm{id}_Y$, then g = h.

Proof. Let $y \in Y$. By the previous theorem we know that f is surjective, so y = f(x), for some $x \in X$. Thus

$$g(y) = g(f(x))$$

$$= x$$

$$= h(f(x))$$

$$= h(y).$$

Thus g = h and the inverse is unique.
